

Is the drop real? Statistical significance

the same 70%, two verdicts

```
n=20: CI=[0.481, 0.855] -- includes 80% -> can't confidently call it a  
regression  
n=200: CI=[0.633, 0.759] -- entirely below 80% -> regression confirmed
```

More samples narrow the interval. The same nominal drop is noise
at $n=20$ and signal at $n=200$ -- report the interval, not just the rate.

A regression threshold without a confidence interval is a coin flip at small n .
